Summary

Krubera-Voronya cave and other deep systems in Arabika Massif are being explored during many speleological expeditions. A recent Ibero-Russian exploration expedition (summer of 2010) took place in this cave with the aim of providing a study of the biocenosis of the deepest known cave in the world. Four new species of Collembola were found at different depths: *Schaefferia profundissima* n. sp., *Anurida stereoodorata* n. sp., *Deuteraphorura kruberaensis* n. sp., and *Plutomurus ortobalaganensis* n. sp., the last one at -1980 m deep. The identification and description of the new species have required the careful study of all congeneric species, implying a revision of each genus. As a result of this work tables and keys to all significant characters for each species are presented.

Keywords

Key; cavernicolous fauna; biospeleology; deepest cave of the world; *Schaefferia profundissima* n. sp.; *Anurida stereoodorata* n. sp.; *Deuteraphorura kruberaensis* n. sp.; *Plutomurus ortobalaganensis* n. sp.

Introduction

Collembola (springtails) are common inhabitants of caves and more than 240 species are considered troglobionts in the Euro-Mediterranean region (Deharveng and Thibaud

1989; Thibaud and Massoud 1986; Thibaud and Dehanverg 1994), but they also are found in cold caves at high elevations. Collembola play an important role in the terrestrial environments of many subterranean communities, frequently consisting of stable and large populations of tiny arthropods feeding on fungi and decomposing organic matter. Until now the deepest-dwelling springtails were *Ongulonychiurus colpus* Thibaud and Massoud, 1986 and *Tritomurus veles* Lukić, Houssin and Deharveng, 2010, found in caves in Spain (-550 m below ground level, bgl) and Croatia (-430 m bgl) respectively (Thibaud and Massoud 1986; Lukić et al. 2010). But a new discovery of a new species of *Plutomurus* (Tomoceridae) at -1980 m deep in Krubera-Voronya cave (also called Voronya Cave or Voronja Cave), the deepest cave of the world reaching the -2191 m bgl (Figure 1, entrance; Figure 2, cave profile), located in the Arabika massif (Western Caucasus), one of the largest karstic massifs in the World. This massif, well-developed at elevations ranging between 1900 and 2500 m above sea level, asl, is composed of Lower Cretaceous and Upper Jurassic limestone's (Klimchouk 2005). Although Krubera-Voronya cave and other deep systems in Arabika Massif, have been explored during many speleological expeditions, especially in the last decade, but their biological components have received little interest.

During the summer of 2010, an Ibero-Russian exploration expedition in the Krubera-Voronya cave took place including a biospeleological study of the biocenosis of the deepest cave on Earth. The objective was to understand the vertical distribution

Figure 1. Krubera-Voronya cave entrance. Photo by Sofia Reboleira.

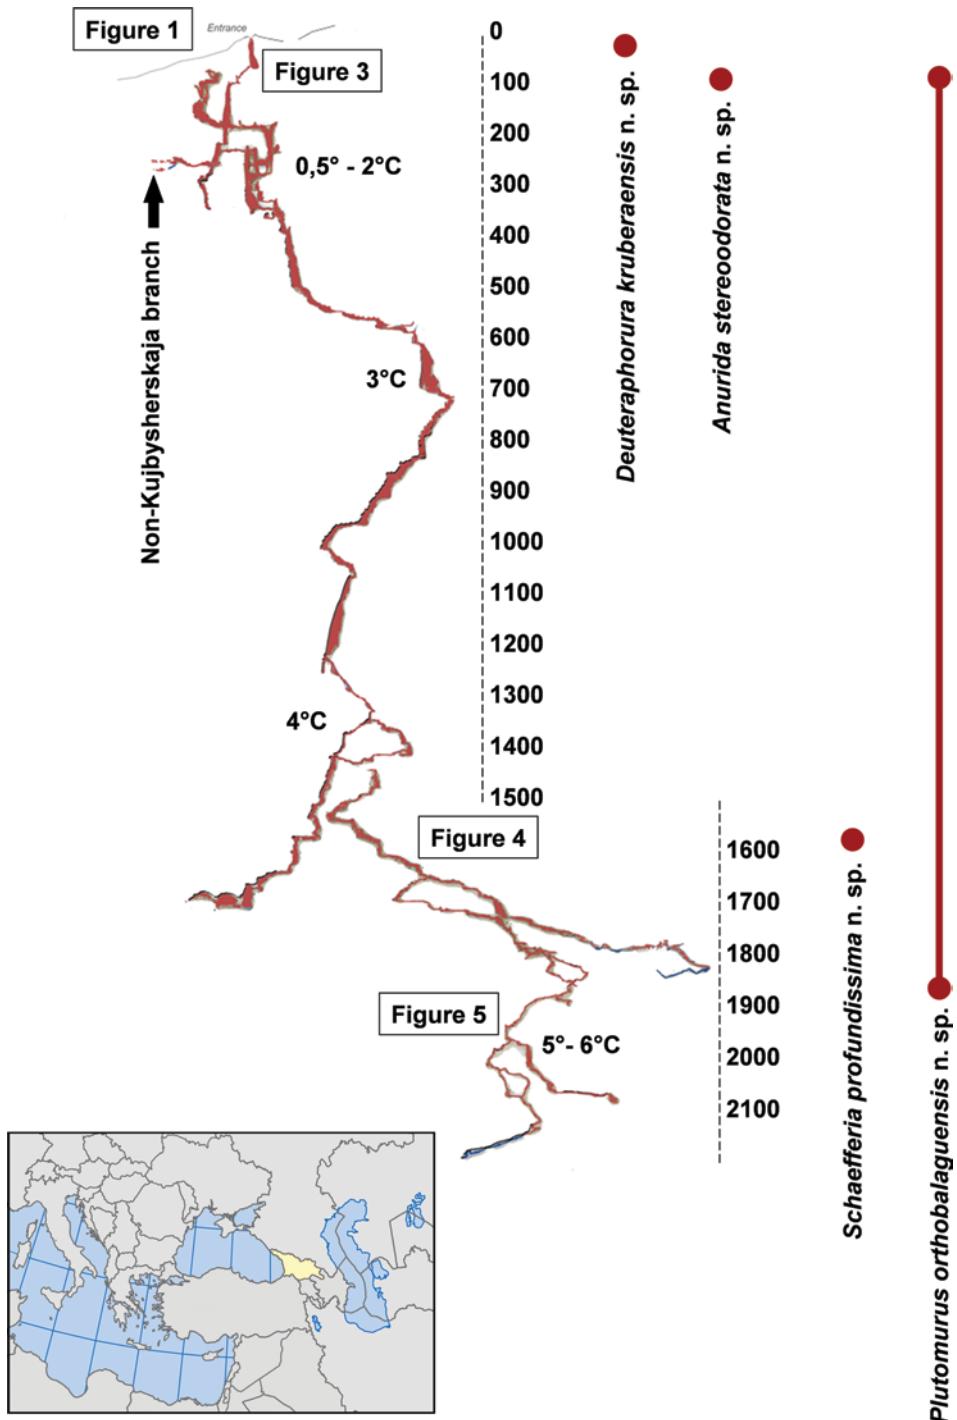

Figure 2. Krubera-Voronya cave profile, location of Figures 1, 3–5, and locations at which new species were found (red dots and red line). Adapted from Ukrainian Speleological Association 2010, compiled by A. Klimchouk.

of the invertebrate fauna in the deepest underground natural place known on Earth (Sendra and Reboleira, unpublished). This lead to the discovery of the species described in the present work which are now the deepest invertebrates ever found below the surface of the Earth. Three other new species have been found at different depths in the same cave.

Despite Krubera-Voronya cave is also inhabited by other hypogean arthropods possessing different degrees of troglomorphy (Sendra and Reboleira, unpublished), but still Collembola play a very important rule in the decomposition and consumer of organic matter. The described new species were found to be the most abundant secondary decomposers in the terrestrial environment of the cave.

In this environment, and at different depths, have appeared, in addition to the new species of *Plutomurus*, new species of *Schaefferia* (Hypogastruridae), *Anurida* (Pseudachorutinae) and *Deuteraphorura* (Onychiurinae).

Materials and methods

Field work was conducted in the Krubera-Voronya cave (UTM: 43° 24' 35" N, 40° 21' 44" E) to a depth of -2140 m bgl by the Ibero-Russian CaveX Team. The cave is located in a disputed political entity on the eastern shore of the Black Sea, southwest of the Caucasus. The cave was monitored for almost one month (from 27.VII.2010 to 24.VIII.2010), from the base of the first shaft, in total darkness at -15 m bgl, to the deepest part of the cave, at the last siphon at -2140 m bgl. Sets of pitfall traps (6 cm diameter and 7 cm deep, with 1 cm diameter tube fixed inside at the centre) were used in the base of the first series of shafts (Figure 3) and in each bivouac (-700 m, -1400 m and -1690 m bgl) (Figures 4 and 5). Traps were partially filled with 1,2-propanediol, and cheese was used as a lure. The traps were supported and covered by small stones in order to prevent flooding. The monitoring of pitfalls was supplemented by several hours of active searching during the visit to the cave.

Specimens were cleared in Nesbitt's fluid and, after washing for one hour in 70% alcohol, were mounted in Hoyer's medium for optical microscope observation. Some specimens were observed with an scanning electron microscope, SEM. Specimens from 70% ethyl alcohol, were slowly rehydrated in a decreasing series of ethyl alcohol. Once in distilled water they were fixed in 4% glutaraldehyde in cacodylate buffer for 24 h, and then transferred to sucrose 0.25 M for 24 h. After this time the specimens are dehydrated up to 100% ethyl alcohol. Complete desiccation was achieved by the CO₂ critical point technique. Samples then were covered by a 16 nm thin layer of molecular gold using an Emitech K550 sputter coater. Observations were done with a Zeiss Digital Scanning Microscope 940 A.

Cave description

The entrance of Krubera-Voronya cave is located at 2240 m asl at 15 km from the Black Sea, through an open air pit of -60 m bgl depth in the slope of the valley.

Figure 3. Location of two or the pitfall traps at -70 m bgl. Photo by Sofía Reboleira.

Figure 4. Bivouac at -1600 m bgl. Photo by Sergio Garcia-Díls.

Figure 5. The cave at -1980 m bgl, the deepest habitat of *Plutomurus ortobalaganensis* n. sp. Photo by Denis Provalov.

The cave (Figure 2) has two main branches of strictly vertical pits separated by short meanders. At -1400 m bgl, in the main branch of the cave, requires cave-diving techniques are required to pass several siphons to the current end of the dry cave, in a last siphon at a depth of -2140 m bgl.

The cave atmosphere has a very constant temperature throughout the year. During the sampling period was possible to record a vertical gradient, increasing from the 0.5 °C in the upper part of the cave, to 5–6 °C at -2000 m bgl (García Dils, pers. comm.). The water flow that goes down by gravity is constant along the cave, which allows deposition of organic matter to the deepest parts of the cave in a short period of time.

Systematic entomology

The following abbreviations are used in this section: Abd I–VI, abdominal segment I–VI; Ant I–IV, Antennal segments I–IV; asl, above sea level; bgl, below ground level; ms, microsensillum/a; PAO, postantennal organ; s, sensillum; Th I–III, thoracic segment I–III.

***Schaefferia profundissima* Jordana and Baquero n. sp.**
 (Figures 6–8)

Type locality

Krubera Cave, Arabika Massif, Gagrinsky Range of the Western Caucasus, Gagra district of Abkhazia (Ortobalagan).

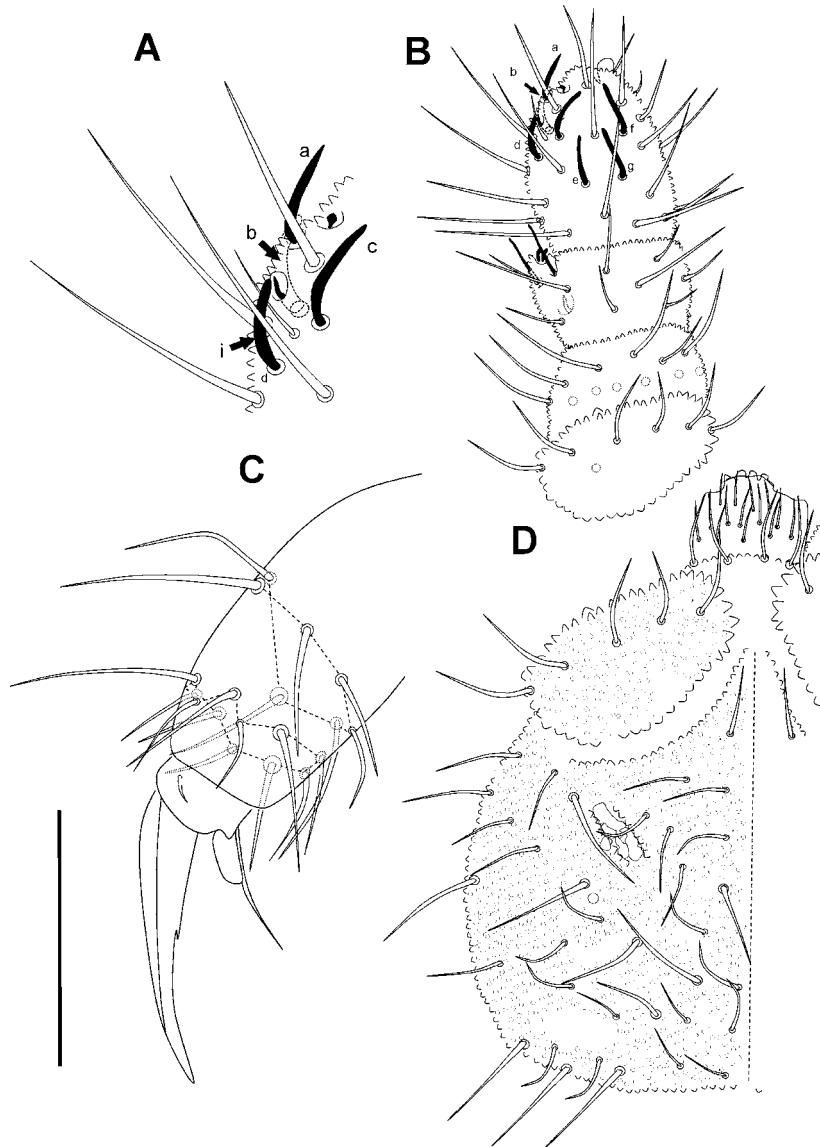

Figure 6. *Schaefferia profundissima* n. sp. (A) Detail of antennal tip (some cylindrical blunt chaetae are named using the nomenclature of Jordana et al. 1997). (B) Antennae. (C) Leg III. (D) Dorsal head.

Type material

Holotype (male) on slide, -1600 m from entrance (that it is at 2420 m asl), shelter 1, from pitfall trap, between 26.VII.2010 to 24.VIII.2010. Coordinates: lat 43.409722°, long 40.362222° (43°24'35.00"N, 40°21'44.00"E). CaveX Team leg. Paratypes (5) on slides (2 males, 2 females and 1 juvenile), same data as holotype. Deposited in Museu de Valencia (Holotype and 4 Paratypes) and MZNA (1 Paratype).

Description

Body length: holotype 1.11 mm (mean of 6 specimens = 0.93 mm). Habitus typical of Hypogastruridae with reduced eyes and furca, fusiform body and differentiated macro and mesochaetae. Yellowish ground colour without any spot of dark pigmentation. Ant I with 6 dorsal cylindrical blunt chaetae. Ant II with 6 dorsal and 6 ventral chaetae in a single row, Ant III sensory organ with 2 central short rods flanked by 2 longer guard sensilla and a small sensillum in a ventral pit, Ant IV with a simple apical vesicle, 7 sensilla or cylindrical blunt chaetae (a, b, c, d, e, f and g) (after Jordana et al. 1997), sub-apical ms and apical sensory peg (Figures 6A–B). 0 to 1 eyes on each side of the head (1 specimen with 0 + 0, 3 specimens with 0 + 1, and 2 specimens with 1 + 1), each eye similar in size to the PAO accessory tubercle, PAO with 4 vesicles (Figure 6D, 8C). Labrum with 4 prelabral chaetae and 5, 5, 4 labral chaetae. Tibiotarsi I–III with 19, 19, 18 chaetae respectively, without capitate tenent hair. Unguis with tooth at the middle of the internal edge. Unguiculus with basal lamella and an apical filament reaching the middle of the unguis edge (Fig 6C). Unguis 50 µm long. Ventral tube with 3 + 3 apical chaetae. Retinaculum with 4 + 4 teeth. Dens length 92 µm, with 5 chaetae. Mucro (34 µm) near 1/3 as dens length (Figure 7A). Anal spines on papillae not fused, of same length as the unguis of leg III (Figure 7B).

Chaetotaxy (Figures 8A–D)

Head: d_2-d_5 (a_0 , d_0 and d_1 absent), sd_1-sd_5 , v_1-v_2 , c_1-c_5 , p_1-p_5 . d_2 , v_2 , oc_1 , oc_3 , g_5 , p_3 and p_4 are macrochaetae. Th I with 3 + 3 chaetae. Th II–III with a_1-a_6 , m_1 , m_4-m_6 (with ms), $p_1-p_4(s)$, p_5-p_6 . Abd I with 5 + 5 chaetae between p_5 s in rows "a" and "m". Abd II–III with 5–7 + 5–7 chaetae between $p_5(s)$ in rows "a" and "m". Abd IV with 7 + 7 chaetae between $p_5(s)$ in rows "a" and "m", and chaeta p_1 shorter than p_2 . Abd V with 2 + 2 chaetae between $p_3(s)$ on row "a". Abd VI with a_1-a_3 , p_1 (anal spine), p_2-p_3 and p_0 present (chaetotaxy follows Jordana et al. 1997).

Discussion

Thirty-four species of *Schaefferia* have been described around the world, mostly in the Palearctic Region with only four species on the Nearctic Region. Thibaud et al. (2004) considered only 28 of them as valid species, synonymising some species. We have revalidated some of these species as due to differences in chaetotaxy. The specimens found by Babenko et al. (1994) from Caucasus identified as *S. vandalica* have differences in chaetotaxy on Abd II–IV compared with the original description for the

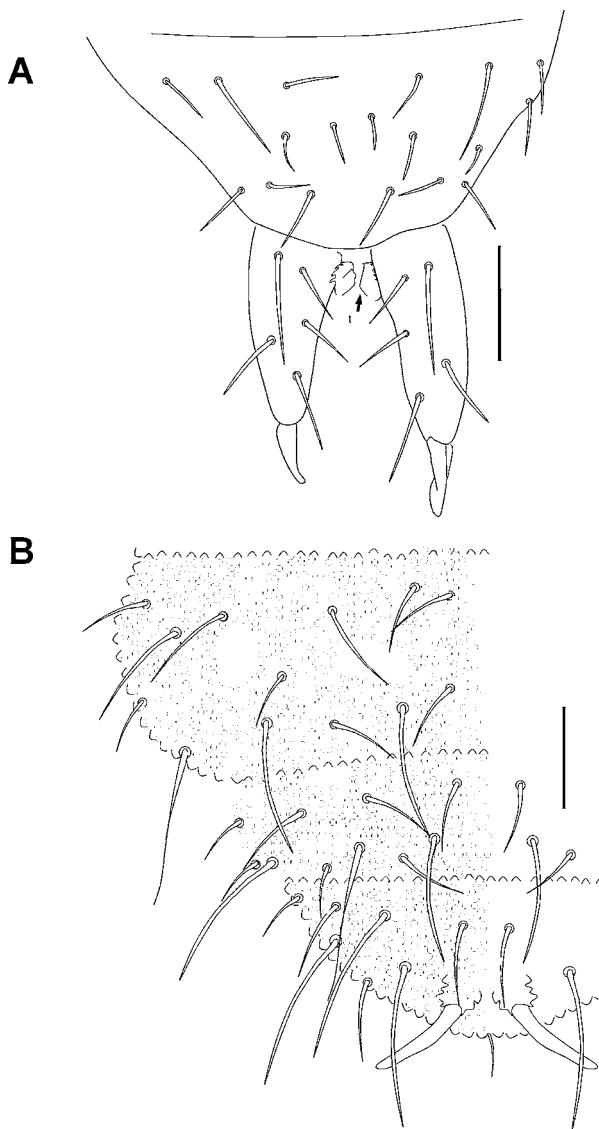

Figure 7. *Schaefferia profundissima* n. sp. (A) Furca (t, tenaculum). (B) Dorsal view of Abd IV–VI, showing small areas without granulation.

species. Again, the specimens identified as *S. duodecimocellata* from Alaska (2700 m asl) by Fjellberg (1985), differs in Abd IV chaetotaxy from the original description of *S. duodecimocellata*.

In the key given below all these species can be separated. The new species has been compared with those with 0–1 eyes: *S. coeca* Cassagnau, 1959, *S. guerrerense* (Bonet, 1945), *S. oaxacana* Palacios-Vargas and Thibaud, 1985, and *S. subcoeca* Deharveng and Thibaud, 1980. The new species shares with *S. oaxacana* the presence of mucron, but

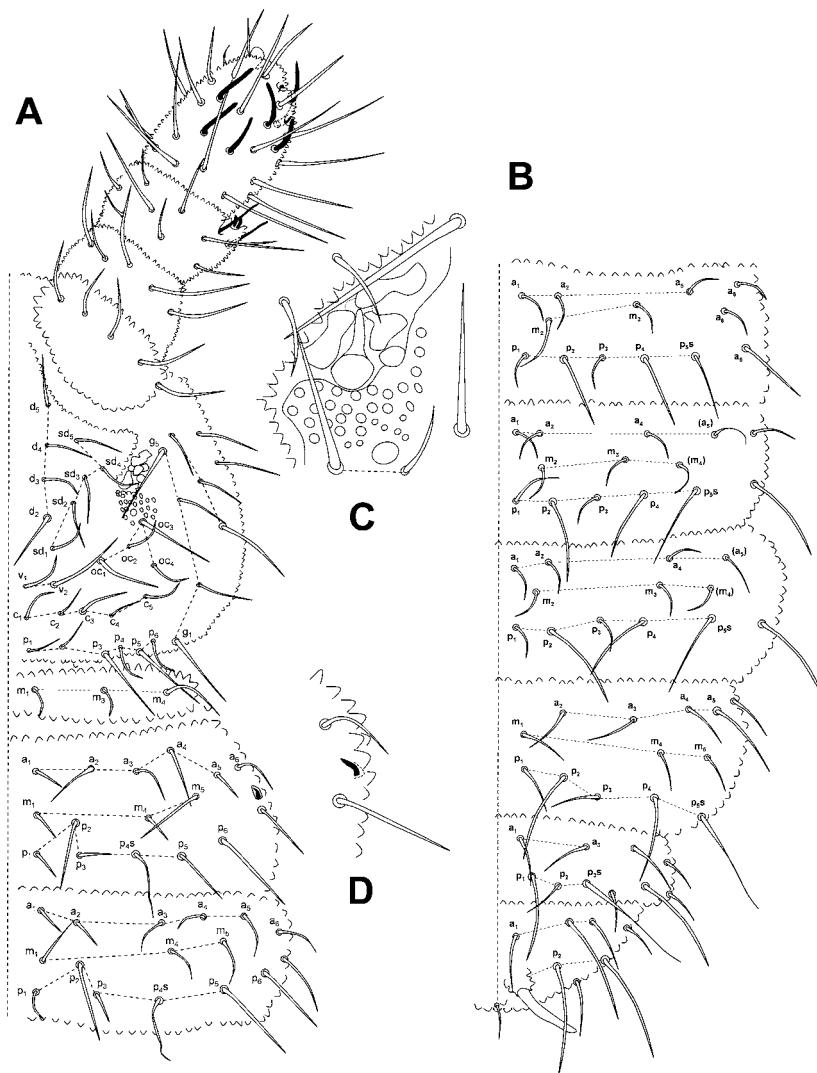

Figure 8. *Schaefferia profundissima* n. sp. chaetotaxy. (A) Dorsal head (with antenna) and Th. (B) Dorsal Abd. (C) Detail of PAO and granulation beside it. (D) Detail of the ms of Th II.

differs from it by the number of chaetae on dens and sensilla on Ant IV. For the preparation of the characters' tables, the original papers and some reviews for the genus has been consulted (see Table 1).

Table 1. World species of *Schaafferia* with its diagnostic characters. Abbreviations: ten, tenaculum; unguis IT, unguis internal teeth; Ant, antennal; Abd, abdominal; a, row a; m, row m; p, row p. The brackets mean that these chaetae occasionally can be missing asymmetrically. ***Anurida stereoodorata* Jordana and Baquero n. sp.**

(Figures 9–11)

Type locality

Krubera Cave (called too Voronya Cave or Voronja Cave), Arabika Massif, Gagrinsky Range of the Western Caucasus, Gagra district of Abkhazia (Ortobalagan).

Type material

Holotype (female) on slide, -70 m from entrance (2420 m above sea level), pitfall trap, between 26.VII.2010 to 24.VIII.2010. Coordinates: lat 43.409722°, long 40.362222° (43°24'35.00"N, 40°21'44.00"E). CaveX Team leg. 4 paratypes (female) on two slides, 2 paratypes on SEM stub and 104 paratypes in ethyl alcohol. Deposited in Museu de Valencia (Holotype and 90 Paratypes) and MZNA (19 Paratypes).

Etymology

The name “*stereoodarata*” derives from the orientation forward of the two chemoreceptors (PAO).

Description

Paratergites on Th and Abd lobed laterally, Abd VI bilobed (Figures 10A, 11A). Holotype (female) length 3.90 mm; paratypes up to 4.5 mm. Colour in alcohol

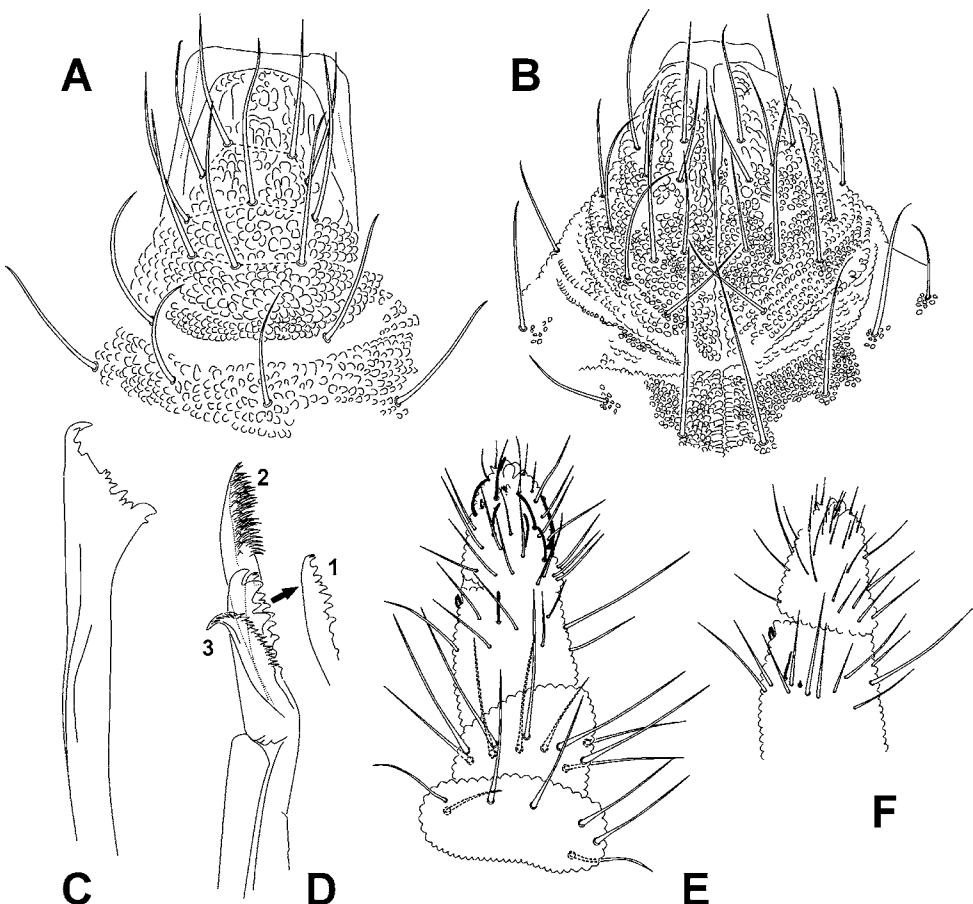

Figure 9. *Anurida stereoodorata* n. sp. (A) Labrum. (B) Labium. (C) Mandible. (D) Maxillary lamellae (after Fjellberg 1985). (E) Antenna. (F) detail of antenna, ventral view.

whitish. Eyes absent. Labral formula interpreted as 4/2334 (Figure 9A). Antennae/head ratio 0.65. Antennal segment IV with 7 blunt sensilla and trilobed apical bulb (Figures 9E–F). External ms and subapical organite present. Antennal segments III and IV fused dorsally. Sensory organ of antennal segment III consisting of two long, widely separated outer sensilla, a small ventral ms and two straight and pointed sensory pegs (Figure 11B). Antennal segment II with 11 chaetae, antennal segment I with 7 chaetae. PAO (Figures 11C–D), dome shaped, with about 60 vesicles with chemoreceptor aspect in its frontal part (Figure 11C–E), directed forward, and probably with stereo-olfactory ability given their position and the environment in which this species lives, in darkness. Mandible with 3 teeth and dentate plate, 10–13 teeth in total (Figure 9C). Maxillary capitulum with a four teeth unguis and three dentate or fringed lamellae (Figure 9D). Labium with 10 chaetae on each side, without papillate L chaeta (Figure 9B). Th I–III and Abd I–IV with lobed laterally paratergites. Female genital plate with 20–26 microchaetae; male genital plate with about 80 microchaetae. Unguis without inner teeth (Figure 10D). Furca completely absent.

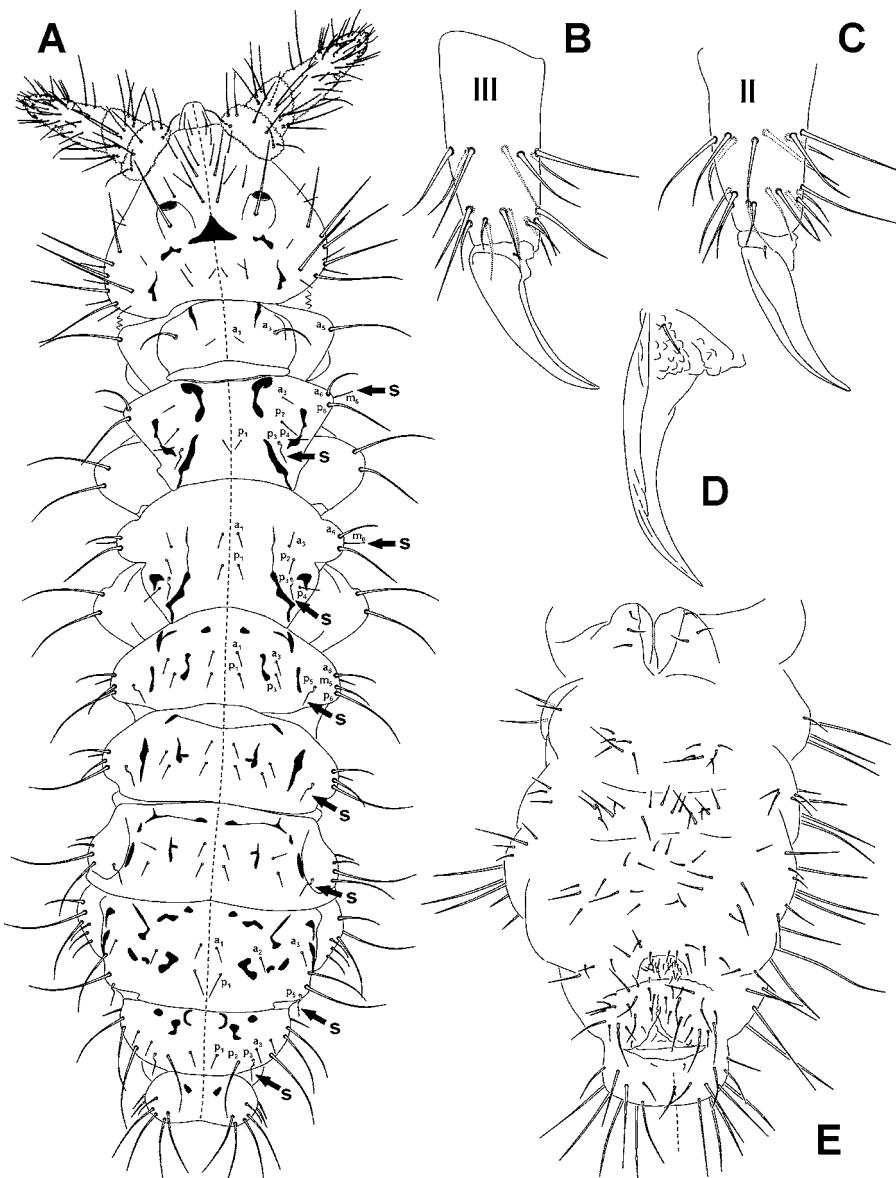

Figure 10. *Anurida stereoodorata* n. sp. (A) Habitus, dorsal view. The black spots means crevices and depressions (see Figure 11A) (the arrows point to the ‘sensory’ chaetae) (B–C) Legs III and II respectively. (D) Unguis, lateral view. (E) Ventral view of Abd.

Chaetotaxy (Figures 10A, 10E)

Macro and microchaetae on body well differentiated; lateral macrochaetae well developed. Th I with $3 + 3$ chaetae; Th II with 8 chaetae, ‘sensory’ chaetae $s = m_6$ and p_3 (the term ‘sensory’ not implying that they have any special sensory function); thoracic terga III with 9 chaetae, ‘sensory’ chaetae $s = m_6$ and p_3 ; Abd I–III with 9 chaetae.

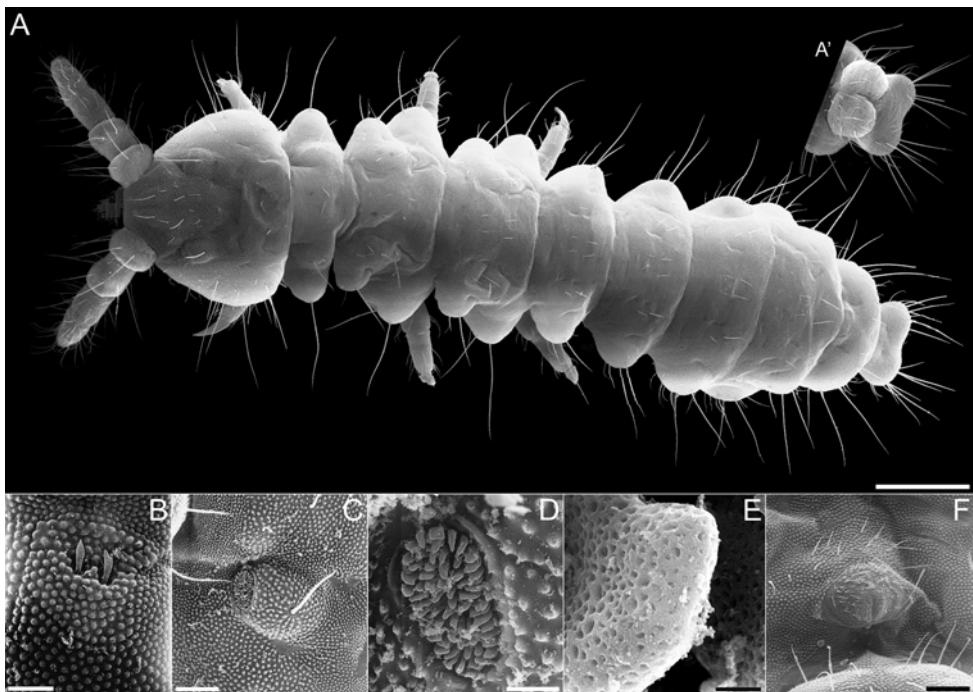

Figure 11. *Anurida stereoodorata* n. sp. SEM microphotographs. (A) Dorsal habitus (A', ventral Abd tip). (B) Sensory pegs of sensory organ of antennal segment III (scale bar: 20 µm). (C–D) PAO (bars: 70 and 20 µm respectively). (E) Detail of a PAO vesicle, showing perforations (scale bar: 1 µm). (F) Male genital plate (scale bar: 60 µm).

Formula of ‘sensory’ chaetae s per half tergum: 022/11111. Ms on Th II present, absent on Th III. Ventral chaetotaxy as in Figure 10E. Ventral tube with 3 + 3 chaetae (Figure 10E). Male genital plate in Figure 11F. Tibiotarsi I, II and III with 19, 19 and 18 chaetae, respectively (Figure 10B–C).

Discussion

Bellinger et al. (1996–2011) defined Pseudachorutinae as Collembola Neanuridae with: 1) mandible present without molar plate; 2) with or without furca (if present could be reduced to one or two knobs with chaetae); 3) sensillar chaetotaxy of Ant IV with fewer or more than 8 sensilla, never with 8; 4) without ms; 5) Abd VI usually not bilobed or truncated (nevertheless some species have this segment more or less truncate); 6) body without finger-like projections; 7) head and first thoracic segment dorsally separated. The triangular head of the maxilla separates it from Friesinae.

Deharveng (2004) hypothesized that Pseudachorutinae was para- or polyphyletic.

Anurida stereoodorata n. sp. could be considered as belonging to a new genus on the basis of the unique PAO and bilobed Abd VI. All other *Anurida* spp. have the PAO tubercles arranged in a circle or ellipse, and none has a bilobed Abd VI.

Thirty-three genera of Pseudachorutinae have the PAO present, but only 9 have some species without eyes (Table 2): *Furculanurida* Massoud, 1967, *Grananurida* Yosii, 1954, *Intermediurida* Najt, Thibaud and Weiner, 1990, *Lanzhorzia* Rusek, 1985 and *Micranurida* Börner, 1901 have needle-like maxilla; *Anurida* Laboulbene, 1865 (71 spp.), *Anuridella* Willem, 1906 (5 spp.), *Minotaurella* Weiner, 1999 (1 sp.) and *Pongeia* Najt and Weiner, 2002 (1 sp.) have dentate or fringed maxillary lamellae. *Anuridella* has a unique form of mandible not present in the new species, *Pongeia* lacks mandibles, and *Minotaurella* has a tuberculate body.

Of the 71 described species of *Anurida*, 35 species lack eyes (Table 3). The PAO is roundish or oval, with vesicles in a single line, and occasionally with some vesicles in the interior part of the external line (morel-like form). Ten species share this characteristic of the PAO (not its dome shaped), and between them, only two species share with the new species the absence of tooth on the inner edge of the unguis: *A. assimilis* Yosii, 1956 and *A. desnuda* Yosii, 1956. *Anurida assimilis* has 45 vesicles in the PAO and *A. desnuda* has 18, while the new species has about 60. In the new species Abd VI is clearly bilobed and Ant IV has 7 sensilla, while the other two species have a rounded Abd VI and 9–10 sensilla on Ant IV. The other species with internal vesicles on an elliptic PAO are: *A. wrangelensis* Tshelnokov, 1988 and *A. frigida* Fjellberg, 1973; each of these species has 12–15 vesicles in PAO and Abd VI is entire.

 - PAO rounded or oval, with symmetric vesicles 39
- 39 Vesicles of PAO narrow or compressed
*A. similis* Fjellberg, 1985 (Alaska and USA, soil)
 - PAO rounded and without compressed vesicles
*A. martynovae* Fjellberg, 1985 (Alaska and Canada)

Deuteraphorura kruberaensis Jordana and Baquero n. sp.

(Figures 12–14)

Type locality

Krubera Cave (called too Voronya Cave or Voronja Cave), Arabika Massif, Gagrinsky Range of the Western Caucasus, Gagra district of Abkhazia (Ortobalagan).

Type material

Holotype (female) on slide, -15 m from entrance (2420 m above sea level), pitfall trap, between 26.VII.2010 to 24.VIII.2010. Coordinates: lat 43.409722°, long 40.362222° (43°24'35.00"N, 40°21'44.00"E). CaveX Team leg. 2 paratypes (male and subadult) on slide, 2 paratypes on SEM stub and 16 paratypes in ethyl alcohol. Deposited in Museu de Valencia (Holotype and 10 Paratypes) and MZNA (10 Paratypes).

Etymology

The species name is derived from the name of the cave (Krubera) where the specimens were collected.

Description

Body length up to 2.2 mm (average 1.6, n = 17), cylindrical, with uniform cuticular granulation except for small areas on all tergites (Figure 12A, dotted line). Colour white in alcohol. Length of Ant I, II, III and IV as 50, 80, 70 and 150 µm. Ratio antennae/head diagonal = 0.72. Antennal base well marked. Ant IV (Figure 12D) with subapical organite and ms at its base, in latero-external position; 30-40 thin chaetae like sensilla, not well distinguishable from chaetae, on the distal two third of Ant IV, in the opposite side of the antennal III sense organ. Antennal III sense organ with two sensory rods, two sensory ribbed clubs (Figure 12B') protected by five papillae and its respective five guard chaetae, and a ventral ms (Figure 12B). PAO consisting of 19–21 compound vesicles disposed in two parallel rows (Figure 12C). Labrum with 4/142 chaetae (Figure 13A). Submentum with 4 + 4 chaetae, basolateral field (mentum) with 5 chaetae; outer maxillary lobe with one basal chaeta and two sublobal hairs. Labial papillae of A type (according to Fjellberg 1999), with six proximal chaetae; labial papillae A, B, C, D, E with 1, 4, 0, 3, 3 guard chaetae respectively (Figure 13B). Mandible with four apical teeth, only the basal slightly different in both mandibles (Figure 13C);

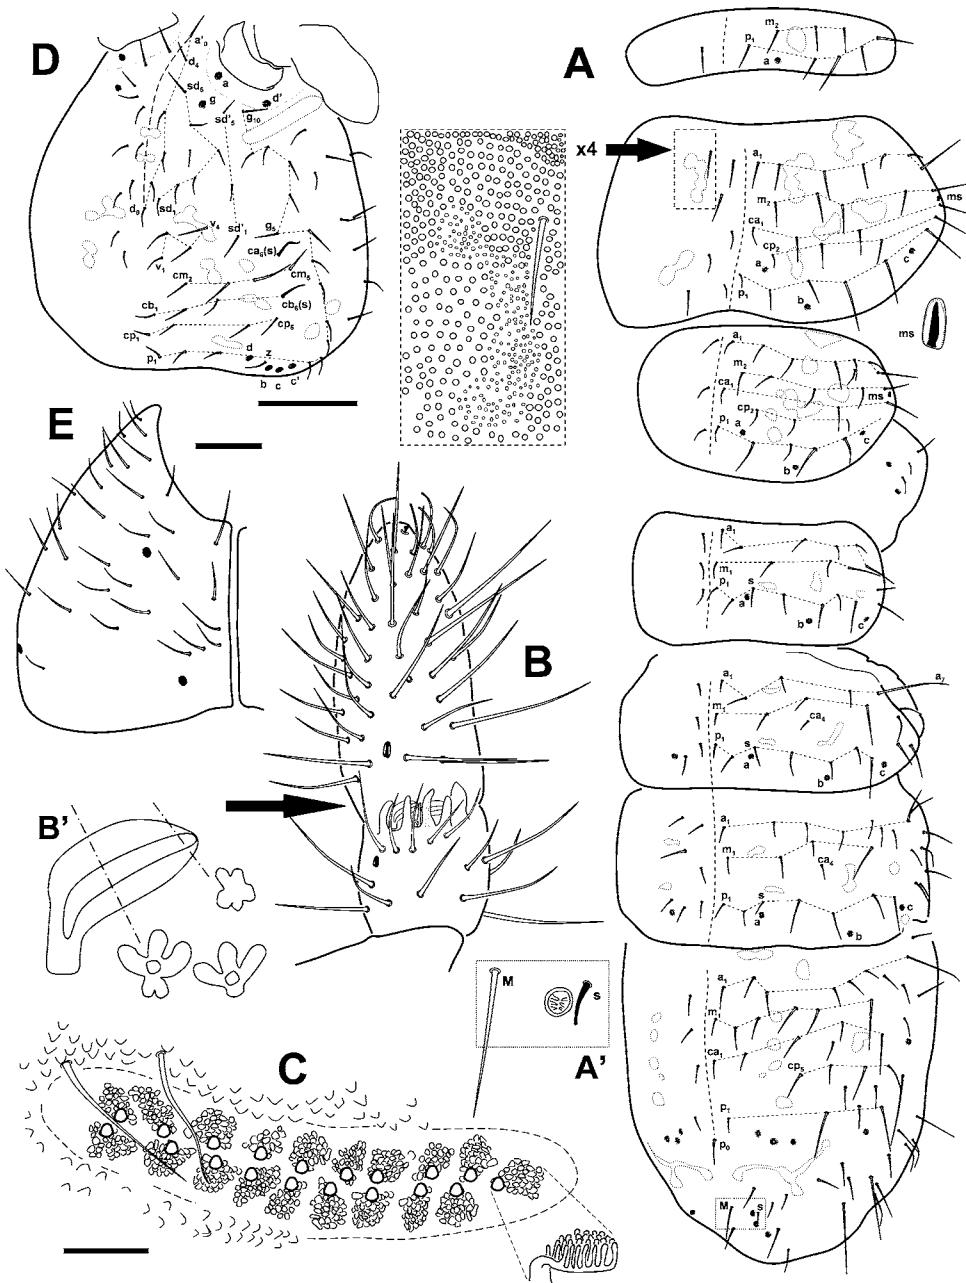

Figure 12. *Deuteraphorura kruberensis* n. sp. (A) Dorsal chaetotaxy of the thoracic and abdominal tergites (A', detail of chaeta M and chaeta s of the tergite V) (scale bar: 100 µm). (B) Ant III–IV (B', detail of the sensory clubs with two sections). (C) PAO (postantennal organ) (scale bar: 20 µm). (D) Dorsal head chaetotaxy (scale bar: 90 µm). (E) Ventral head chaetotaxy (scale bar: 60 µm).

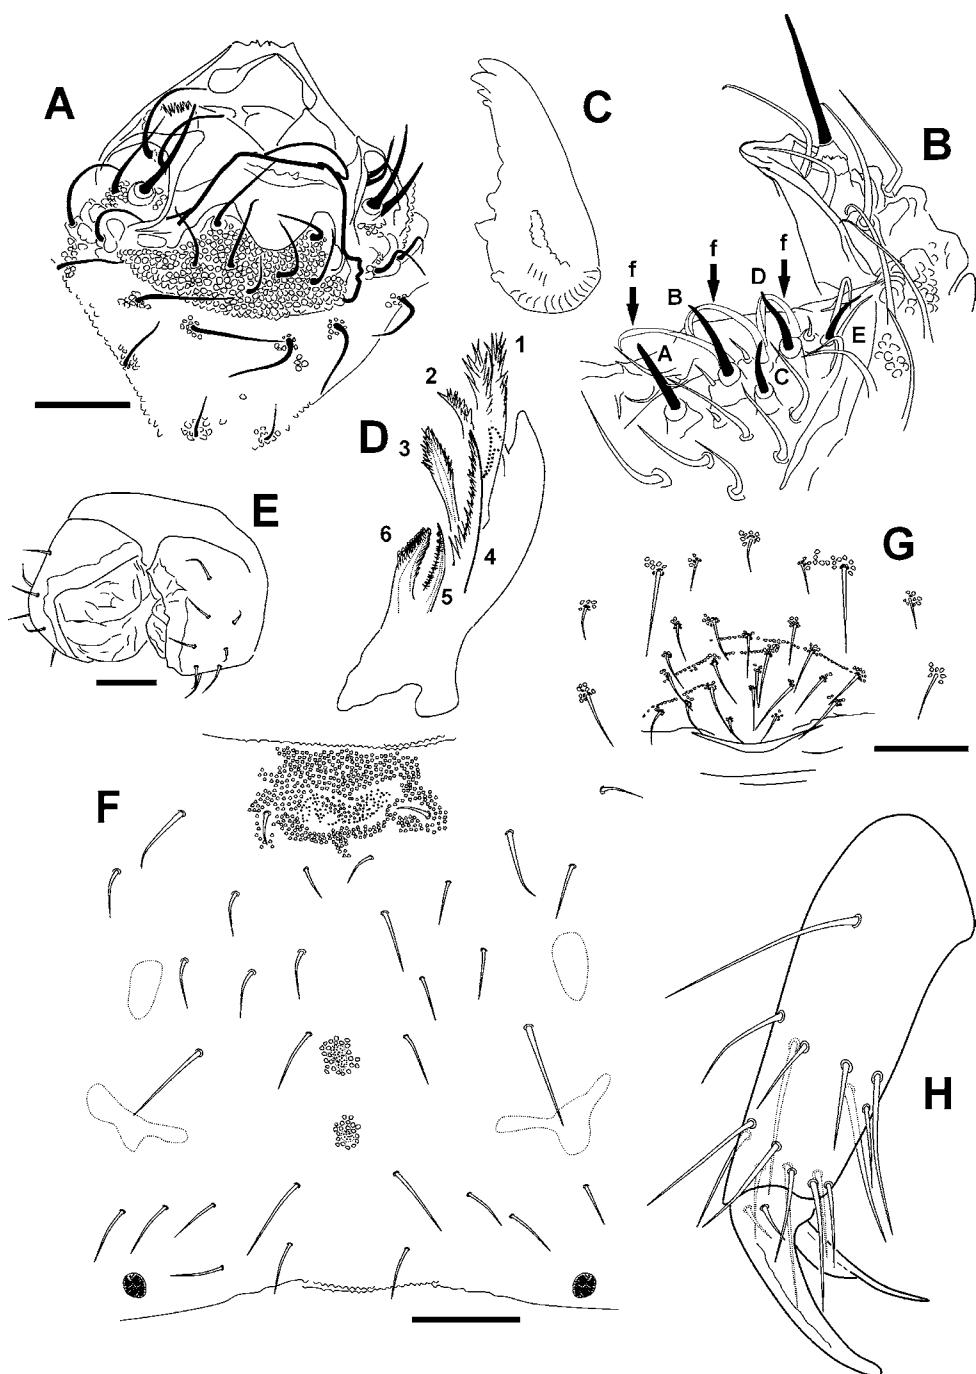

Figure 13. *Deuteraphorura kruberaensis* n. sp. (A) Labrum chaetotaxy (scale bar: 40 µm). (B) Labial palp chaetotaxy (labial papillae A, B, C, D and E) and outer maxillary lobe (f: flattened chaetae). (C) Mandible. (D) Maxilla. (E) Ventral tube (scale bar: 40 µm) (F) Ventral view of Abd IV, with the vestigial furca at the top (scale bar: 50 µm). (G) Detail of the female genital aperture (scale bar: 40 µm). (H) Tibiotarsus, unguis and unguiculus of leg III.

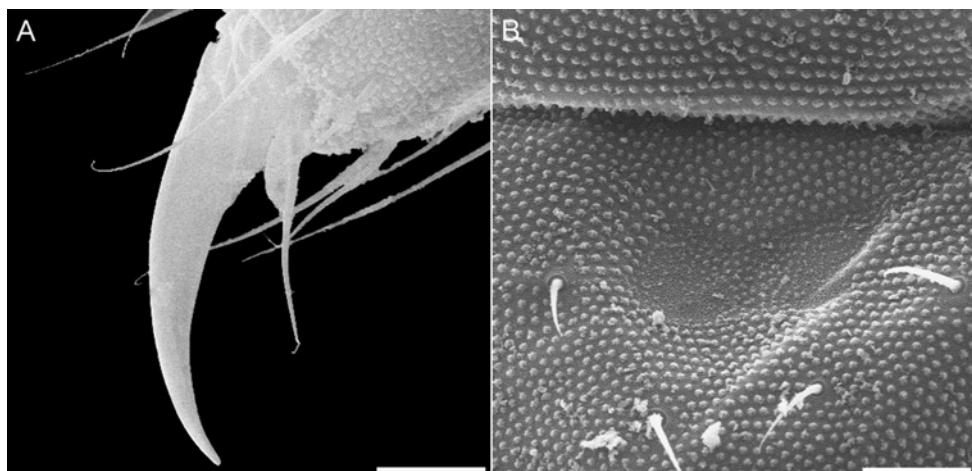

Figure 14. *Deuteraphorura kruberaensis* n. sp. SEM microphotographs. (A) Unguis and unguiculus of leg III. (B) Area of vestigial furca (bar, A and B: 20 μ m).

Table 4. *Deuteraphorura kruberaensis* n. sp. head chaetotaxy. Abbreviations: m, microchaeta; M, macrochaeta; s, sensilla; z, chaeta z. “-” denotes: absence of chaeta.

maxillary head as in Figure 13D. Unguis without inner or outer teeth; unguiculus with basal lamella (Figures 13H, 14A). Ventral tube with 8 + 8 apical chaetae, without basal chaetae (Figure 13E). Furca reduced to a finely granulated area with 1 + 1 small chaetae backward (Figures 13F and 14B). Typical dorsal pseudocellar formula 34/133/33353, but frequently variable, specially on Abd IV (3–5 pseudocelli), common disposition on Abd IV 3 + 1 + 1 from dorsal axis to lateral, sometimes 1 + 0 + 2. Ventral pseudocellar formula 3/011/31110. Subcoxae 1 of all legs each with 2 pseudocelli.

Chaetotaxy

Lateral ms on Th II and III. Distribution of dorsal chaetae as in Figure 12A, 12D and Tables 4–6; asymmetries are common. Chaeta p_0 present on Abd IV and VI. Ratio chaetae M/s = 2.7 on Abd V; longest macrochaetae on Abd VI: 110 μm . Without chaetae on ventral thoracic sternites; ventral chaetotaxy of head as in Figures 12D (dorsal) and 12E (ventral). Female genital area with 20 chaetae (Figure 13G).

Tibiotarsi I, II, and III with 18, 18 and 17 chaetae respectively; distal whorl with 9 chaetae.

Table 7. World species of *Deuteraphorina* with its diagnostic characters. Occasional number of pseudocelli between brackets. Abbreviations: PAO, Post Antennal Organ; Ant O III, Antennal Organ III; ves n°, vesicles number; c, composed; s, simple; pap n°, number of guard papillae; s, smooth; r, rough; ant, anterior; post, posterior; Th, thorax; Abd, abdomen. “-” denotes: no data available.

Discussion

The characters used by Weiner (1996) and Pomorski (1998) in the diagnosis of the genus *Deuteraphorura* are: PAO with compound vesicles, sensory clubs in Ant III organ ovoid, curved (or bent), smooth with one or two ribs in the middle, sensilla on Ant IV slightly marked, two stout sensilla present, and microsensillum (ms) at $\frac{1}{4}$ the length of the segment, base of antenna well marked, posterior pseudocelli on the head present, Th I with $1 + 1$ or $0 + 0$ pseudocelli, tergites from Th II to Abd III with few pseudocelli, Abd IV and V with $4-5 + 4-5$ and $3 + 3$ pseudocelli respectively, sensilla(s) on the body differentiated, rather well marked on the head ($2 + 2$) and Abd V and VI, chaeta d_0 on the head present, Abd VI with two rows of chaetae, a_0 present, anal spines absent, furcal rudiment with finely granulated area and four small chaetae posteriorly, two manubrial row of chaetae present. The new species has all these characters except the last two: furcal rudiment with finely granulated area and two small chaetae posteriorly, relatively backward, and more than two manubrial row of chaetae.

To ascertain the nature of the latter two characters, we studied the type series of *D. ameskoana* (Beruete et al., 2001), *D. aralarensis* (Beruete et al., 2001), *D. boneti* Gisin, 1953 (Beruete et al., 2001), *D. doneztebensis* (Beruete et al., 2001), *D. labainensis* (Beruete et al., 2001), *D. leitzaensis* (Beruete et al., 2001) and *D. zalbidensis* (Beruete et al., 2001). In those, we observed considerable intraspecific variation, including four small chaetae in a row, four small chaetae in an asymmetric row, four small chaetae in a trapezoidal disposition (with the lesser wide backward), two (in some cases three) small chaetae. In all these species, there are three or four manubrial rows of chaetae. Therefore, we consider that these small differences do not justify erecting a new genus. Also, we have avoided those characters in the key to the species of *Deuteraphorura*.

Deuteraphorura contains 77 described species (Table 7). This new species belongs to a group of 10 species with four posterior dorsal cephalic pseudocelli; these species occur in European caves, mostly in Spain (Gisin, 1953, 1962; Gruia, 1965; Neuertz and Nosek, 1976 and Beruete et al., 2001): *D. ameskoana*, *D. aralarensis*, *D. boneti*, *D. closanica* (Gruia, 1965), *D. diaelleni* (Neuhertz and Nosek, 1976), *D. doneztebensis*, *D. labainensis*, *D. leitzaensis*, *D. quadrisilvaria* (Gisin, 1962) and *D. zalbidensis*. They can be distinguished from *D. kruberaensis* n. sp. by the following characteristics: *D. leitzaensis* has two pseudocelli on dorsal Th I; *D. closanica* and *D. diaelleni* has more-like (after Weiner, 1996) sensory clubs in antennal III sense organ; *D. ameskoana*, *D. boneti*, *D. doneztebensis* and *D. zalbidensis* have four pseudocelli on ventral abdominal tergite I, and *D. aralarensis*, *D. labainensis* and *D. quadrisilvaria* have two ventral pseudocelli on abdominal sternite II.

Key to the world species of *Deuteraphorura*

alcohol). Deposited in Museu de Valencia (Holotype and 3 Paratypes) and MZNA (2 Paratypes).

Etymology

From Ortobalagan, meaning “nearby settlement”.

Description

Body length up to 3.8 mm excluding antennae (mean 3.0 with $n = 16$). Body background greyish, with patches of darker pigmentation over the whole body except on antennae, legs (trochanter to tibiotarsi) and dentes; colour pattern as in Figure 15A.

Head. Eye patch small, divided into two subpatches but without exterior corneoles (as seen with SEM). Ratio body/antennae length 0.8 ($n = 2$). Prelabral chaetae: 3 + 3, labrum 5, 5, 4 and 4 curved chaetae on distal part of labrum (Figure 15B).

Body. Trochanteral organ well developed on trochanter and femur, with 17/40 chaetae respectively, a few chaetae longer than the rest (Figure 15C). Ventral tube with 35–40 chaetae. Spine-like chaetae absent on tibiotarsus I and II, 1 such chaeta on tibiotarsus (formula 001) (Figure 15D). Unguis with 1 or 2 internal teeth (if 2, paired), at 40% of the unguis length from the base of unguis; unguiculus blade-like, with serrate external edge after middle point, and almost to its tip (Figure 16A–B); tenent hair very short, pointed (0.27 times length of unguis). Ratio of unguis, unguiculus and tenent hair 17:10:5. Unguis with a thin pseudonychia, 0.42 times length of inner edge of unguis. Tenaculum with 4 + 4 teeth and 1 chaeta on corpus (Figure 15F). Ratio of manubrium, dens and mucro 5.4 : 8.6 : 1. Outer margin of dens with 3 thick spine-like chaetae. Dental formula: 7–9 I / I 2–3 I 2–3 I 2 I (dental big spines in Roman and bold) (Figure 15E). Mucro with 2 basal, fused denticles, without subapical denticles, and 2 distal teeth (Figures 15G, 16C–D).

Chaetotaxy

Macrochaetotaxy and trichobothrial patterns in Figure 15H. Dorsal macrochaetae: Th II–III with 6–2 macrochaetae respectively; Abd I–VI with 3–3–4–1–3–3 macrochaetae respectively. Trichobothrial formula 0/2–1/0–0–1–2–0. Trichobothrium with 1–3 small anterior chaetae.

Discussion

Of the 26 known *Plutomurus* spp. (Table 8) 9 lack eyes altogether. *Plutomurus ortobalaganensis* n. sp. differs from these 9 species by the following combination of characters: 3 + 3 prelabral chaetae; subapical denticles lacking on mucro; unguiculus with internal teeth, and dental spine formula 7–9 I / I 2–3 I 2–3 I 2 I. Five of the 9 species have 3 + 3 prelabral chaetae, but only 2 of the 5 have a similar mucronal denticles formula: 2/0/2 (basal/subapical/apical); *P. kawasawai* has no denticles on unguiculus. The remaining species, *P. iwatensis*, can be distinguished by its dental spine formula (9 3/I 1 I 1 I 2 I) and the trochanteral organ (10/15 chaetae on trochanter and femur

respectively). Three *Plutomurus* spp. have been described from Georgia (*P. abchasicus*, *P. birsteini* and *P. kelasuricus*), but all have six eyes on each side.

Key to the world species of Plutomurus

(In the dental spine formula “I” denotes “large spine”).

- 1 With 6 eyes on each side of the head 2
- With fewer than 6 eyes 14
- 2 With subapical denticles on mucro 3
- Without subapical denticles on mucro 7
- 3 Two to four subapical denticles on mucro 4
- One subapical denticle on mucro 5
- 4 Unguiculus without tooth *P. vigintiferispina* Lee, 1974 (South Korea, cave)
- Unguiculus with 1 tooth *P. wilkeyi* Christiansen, 1964 (USA, cave)
- 5 Mucro with 1 basal tooth 6
- Mucro with 2 basal teeth
..... *P. carpaticus* Rusek and Weiner, 1978 (Carpathian, mts., cave & soil)
- 6 Unguis with 1–2 internal teeth; dental spine formula 4–7 I-II/3–4 I 3–6 I
..... *P. brevimucronatus* Denis, 1928 (USA, soil and cave)
- Unguis with 3 internal teeth; dental spine formula 5–8/5 I 2 I
..... *P. edaphicus* Yosii, 1967 (Japan, soil)
- 7 Tenent hair clavate 8
- Tenen hair pointed 13
- 8 Unguiculus without internal tooth
..... *P. birsteini* Djanashvili and Barjadze, 2011 (Georgia, cave)
- Unguiculus with internal tooth 9
- 9 Dental spine formula 5 I/9 I *P. unidentatus* (Börner, 1901) (Europe, cave)
- Different dental spine formula 10
- 10 Spine-like chaetae on tibiotarsus I, II and III: 011
..... *P. borealis* Suma, 1981 (Japan, soil)
- Spine-like chaetae on tibiotarsus I, II and III: 001, 012 or 002 11
- 11 Mucro with 1 basal tooth; dental spine formula 4–6 I –2/12 I; one spine-like
chaeta on tibiotarsi II and two on tibiotarsi III
..... *P. belozerovi* Martynova, 1977 (Sakhalin Isl. Russia, soil)
- Mucro with 2 basal teeth 12
- 12 One spine-like chaeta on tibiotarsus III; dental spine formula 4–5 I /6 I 3 I
..... *P. jeleznovodski* Kniss and Thibaud, 1999 (Caucasus, Russia, cave)

- Two spine-like chaetae on tibiotarsus III; dental spines formula 6–9/9–13 I.....
..... *P. baschkiricus* (Skorikov, 1900) (Europe, cave)
- 13 One spine-like chaetae on tibiotarsus III; prelabral chaetae 3 + 3.....
..... *P. kelasuricus* Martynova, 1969 (Georgia, cave)
- Two spine-like chaetae on tibiotarsus III; prelabral chaetae 2 + 2.....
..... *P. abchasicus* Martynova, 1969 (Abkhazia, cave)
- 14 With 4–5 eyes 15
- With fewer than 4 eyes 16
- 15 With 3 or 4 subapical denticles on mucro
..... *P. riugadoensis* (Yosii, 1939) Yosii, 1956 (Japan, cave)
- Without subapical denticles on mucro.....
..... *P. sorosi* Kniss and Thibaud, 1999 (Russia, cave)
- 16 With 3 eyes *P. leei* Yosii, 1966 (South Korea, cave)
- Without or with 2 eyes 17
- 17 With 2 eyes *P. diversispinus* Yosii, 1966 (South Korea, cave)
- Without eyes 18
- 18 Prelabral chaetae 4 + 4..... *P. marmorarius* Yosii, 1967 (Japan, cave)
- Prelabral chaetae 2 + 2 or 3 + 3..... 19
- 19 Prelabral chaetae 3 + 3 20
- Prelabral chaetae 2 + 2 25
- 20 Without subapical denticles on mucro..... 21
- With subapical denticles on mucro..... 23
- 21 Unguiculus without internal tooth *P. kawasawai* Yosii, 1956 (Japan, cave)
- Unguiculus with internal tooth..... 22
- 22 Dental spine formula 9 3/ I 1 I 1 I 2 I *P. iwatensis* Yosii, 1991 (Japan, cave)
- Dental spine formula 7–9 I / I 2–3 I 2–3 I 2 I *P. ortobalaganensis* n. sp.
- 23 Unguis with 3 or 4 internal teeth.....
..... *P. grahami* Christiansen, 1980 (USA, cave & soil)
- Unguis with 1 or 2 internal teeth..... 24

- 25 Without subapical denticles on mucro..... *P. yamatensis* Yosii, 1956 (Japan, cave)
- With subapical denticles on mucro..... 26
- 26 With 1 subapical denticle on mucro..... *P. suzukaensis* Yosii, 1956 (Japan, cave)
- With 4 subapical denticles on mucro.....
..... *P. californicus* (Folsom, 1913) (California, cave).

Acknowledgements

We express our gratitude to the CaveX Team, especially to Sergio Garcia-Dils, Pilar Orche and to Javier Le Pera for their kind support and cooperation in sampling. All specimens were collected under the permit of Abkhazia government, included in the CaveX Ibero-Rusian Team Expedition, from July to August of 2010. Kenneth Christiansen and several anonymous reviewers provided excellent comments and suggestions that improved this manuscript.
